

1. In which ITSM Process would the Progress Iteratively with Feedback principle apply best?

The Progress Iteratively with Feedback principle applies best to the Continual Service Improvement (CSI) process because CSI relies on constantly evaluating and refining services. By breaking tasks into smaller, manageable parts and gathering feedback after each step, the organization can fix oversights early and deliver real value quickly without getting overwhelmed.

2. How can the Collaborate and Promote Visibility principle help the Service Design process?

The Collaborate and Promote Visibility principle helps the Service Design process by encouraging open communication and teamwork while turning ideas into structured IT solutions. Sharing progress and feedback openly prevents misunderstandings, avoids costly mistakes, and ensures the designed service truly fits the needs of the organization.

3. Between Service Transition and Service Operation, which process would benefit more from the Optimize and Automate principle?

Service Operation benefits more from the Optimize and Automate principle because it covers the recurring, day-to-day delivery of IT services and user requests. Automating these frequent and repetitive tasks saves time, reduces human error, and frees up workers to focus on more complex issues.

4. What would happen if the "Start Where You Are" principle is not observed in the "Continual Service Improvement" process?

If the "Start Where You Are" principle is ignored in Continual Service Improvement, the organization risks wasting valuable time and money by discarding working systems and starting over from scratch. Without building on existing strengths and available resources, the improvement process becomes unnecessarily complicated and expensive.
